US-PAT-NO: 6159354  
DOCUMENT-IDENTIFIER: US 6159354 A  
TITLE: Electric potential shaping method for electroplating

----- KWIC -----

US Patent No. - PN (1):  
6159354

## United States Patent [19]

Contolini et al.

[11] Patent Number: 6,159,354

[45] Date of Patent: Dec. 12, 2000

[54] ELECTRIC POTENTIAL SHAPING METHOD  
FOR ELECTROPLATING

[75] Inventors: Robert J. Contolini, Lake Oswego;  
Jonathan Reid, Sherwood; Evan  
Patton, Portland; Jughin Feng, Tigard;  
Steve Taafjes, West Linn, all of Oreg.;  
John Owen Dukovic, Pleasantville,  
N.Y.

[73] Assignees: Novellus Systems, Inc., San Jose,  
Calif.; International Business  
Machines, Inc., New York, N.Y.

[21] Appl. No.: 08/970,120

[22] Filed: Nov. 13, 1997

### [57] ABSTRACT

An apparatus for depositing an electrically conductive layer  
on the surface of a wafer comprises a flange. The flange has  
a cylindrical wall and an annulus attached to a first end of the  
cylindrical wall. The annulus shields the edge region of the  
wafer surface during electroplating reducing the thickness of  
the deposited electrically conductive layer on the edge  
region. Further, the cylindrical wall of the flange can be  
provided with a plurality of apertures adjacent the wafer  
allowing gas bubbles entrapped on the wafer surface to  
readily escape.

TITLE: Electro-chemical deposition system and method of electroplating on substrates

----- KWIC -----

Drawing Description Text - DRTX (8):

FIG. 4 is a schematic diagram of the electrical circuit representing the electroplating system through each contact pin and resistors.

Detailed Description Text - DETX (8):

Typically, one power supply is connected to all of the contact pins of the cathode contact member, resulting in parallel circuits through the contact pins. As the pin-to-substrate interface resistance varies, between pin locations, more current will flow, and thus more plating will occur, at the site of lowest resistance. However, by placing an external resistor in series with each contact pin, the value or quantity of electrical current passed through each contact pin becomes controlled mainly by the value of the external resistor, because the overall resistance of each contact pin-substrate contact plus the control resistor branch of the power supply to substrate circuit is substantially equal to that of the control resistor. As a result, the variations in the electrical properties between each contact pin do not affect the current distribution on the substrate, and a uniform current density results across the plating surface which contributes to uniform plating thickness. To provide a uniform current distribution between each of the contact pins 56 of the radial array configuration of cathode contact member 52, both during the plating cycle on a single substrate and between substrates in a plating run of multiple substrates, an external resistor 58 is connected in series with each contact pin 56. FIG. 4 is a schematic diagram of the electrical circuit representing the electroplating system through each contact pin of the cathode contact member 52 and the external resistor 58 connected in series with each contact pin 56. Preferably, the resistance value of the external resistor (R.sub.EXT) 58 is greater than the resistance of any other resistive component of the circuit. As shown in FIG. 4, the electrical circuit through each contact pin 56 is represented by the resistance of each of the components connected in series with the power supply. R.sub.E represents the resistance of the electrolyte, which is typically dependent on the distance between the anode and the cathode and the composition of the electrolyte solution. R.sub.A represents the resistance of the electrolyte adjacent the substrate plating surface within the double layer and the boundary layer. R.sub.S represents the resistance of the substrate plating surface, and R.sub.C represents the resistance of the cathode contacts 56. Preferably, the resistance value of the external resistor (R.sub.EXT) is greater than the total of R.sub.E, R.sub.A, R.sub.S and R.sub.C, e.g.,  $R_{EXT} > 1.0 \text{ } \Omega$ . Preferably, the external resistor 58 also provides a uniform current distribution between different substrates of a process-sequence.

Detailed Description Text - DETX (9):

As each substrate is plated, and over multiple substrate plating cycles, the

## ABSTRACT

The invention provides an apparatus and a method for achieving reliable, consistent metal electroplating or electrochemical deposition onto semiconductor substrates. More particularly, the invention provides uniform and void-free deposition of metal onto metal seeded semiconductor substrates having sub-micron, high aspect ratio features. The invention provides an electrochemical deposition cell comprising a substrate holder, a cathode electrically contacting a substrate plating surface, an electrolyte container having an electrolyte inlet, an electrolyte outlet and an opening adapted to receive a substrate plating surface and an anode electrically connect to an electrolyte. Preferably, a vibrator is attached to the substrate holder to vibrate the substrate in at least one direction, and an auxiliary electrode is disposed adjacent the electrolyte outlet to provide uniform deposition across the substrate surface. Preferably, a periodic reverse current is applied during the plating period to provide a void-free metal layer within high aspect ratio features on the substrate.

TITLE:

Method and apparatus for uniform electroplating of integrated circuits using a variable field shaping element

----- KWIC -----

Brief Summary Text - B5TX (10):

The seed layer initially has a significant resistance radially from the edge to the center of the wafer because the seed layer is initially very thin. This resistance causes a corresponding potential drop from the edge where electrical contact is made to the center of the wafer. These effects are reported in L. A. Gochberg, "Modeling of Uniformity and 300-mm Scale-up in a Copper Electroplating Tool", Proceedings of the Electrochemical Society (Fall 1999, Honolulu Hawaii); and E. K. Broadbent, E. J. McInerney, L. C. Gochberg, and R. L. Jackson, "Experimental and Analytical Study of Seed Layer Resistance for Copper Damascene Electroplating", Vac. Sci. & Technol. B17, 2584 (November/December 1999). Thus, the seed layer has a nonuniform initial potential that is more negative at the edge of the wafer. The associated deposition rate tends to be greater at the wafer edge relative to the interior of the wafer. This effect is known as the 'terminal effect'.

Brief Summary Text - B5TX (19):

Regarding the trend towards larger diameter wafers, it is generally understood that the deposition rate, as measured by layer thickness, can be maintained by scaling total current through the electrochemical reactor in proportion to the increased surface area of the larger wafer. Thus, a 300 mm wafer requires 2.25 times more current than does a 200 mm wafer. Electroplating operations are normally performed by using a clamshell wafer holder that contacts the wafer only at its outer radius. Due to this mechanical arrangement, the total resistance from the edge of the wafer to the center of the wafer is independent of the radius. Nevertheless, with the higher applied current at the edge of the larger wafer, which is required to maintain the same current density for process uniformity, the total potential drop from the edge to the center of the wafer is greater for the larger diameter wafer. This circumstance leads to an increased rate of deposition (layer thickness) with radius. While the problem of increasing deposition rate with radius exists for all wafers, it is exacerbated in the case of larger wafers. At sufficiently large wafer sizes, the difference in current density at the center versus the edge will lead to incomplete fill at one of those locations.

## ABSTRACT

An electrochemical reactor is used to electrofill damascene architecture for integrated circuits. A shield is used to screen the applied field during electroplating operations to compensate for potential drop along the radius of a wafer. The shield establishes an inverse potential drop in the electrolytic fluid to overcome the resistance of a thin film seed layer of copper on the wafer.

US-PAT-NO: 6299751  
DOCUMENT-IDENTIFIER: US 6299751 B1  
TITLE: Apparatus and method for plating wafers, substrates and other articles  
----- KWIC -----

Brief Summary Text - BSTM (15):  
A seventh aspect of the invention is an apparatus and method for plating a wafer that is particularly useful in improving the uniformity of the plating deposition across the surface of the wafer when the wafer is initially being plated. When the wafer is initially being plated, the surface resistance of the wafer is high due to the high resistive properties of the seed layer (e.g. copper seed layer). As a result, more of the plating is deposited where the cathode makes contact to the wafer (e.g. at the perimeter of the wafer). This aspect of the invention comprises providing a secondary cathode situated near the cathode contact of the wafer to reduce the plating rate near the cathode contact in response to a control voltage that is more negative than the cathode. The more negative voltage on the secondary cathode diverts plating ions that would otherwise be deposited near the cathode contact. The control voltage is selected to improve the uniformity of the plating deposition across the surface of the wafer.

Detailed Description Text - DETX (22):  
In the preferred embodiment, the cathode contact comprises an electrical-conductive fluid, such as a mixture of sulfuric acid and de-ionized (DI) water. The conductive fluid is significantly advantageous because it provides a uniform contact along and within the exclusion zone (i.e. the contact has a uniform resistance along and within the exclusion zone). Because of the continuity of the cathode contact provided by the conductive fluid, a more uniform plating deposition and higher currents for increasing the plating rate results. Alternatively, a mechanical contact comprising a plurality of equally spaced contacts can be provided along and within the exclusion zone to effectuate the cathode contact to the wafer.

Detailed Description Text - DETX (64):  
The advantage of using a conductive fluid versus a mechanical contact in making the cathode connection to the wafer 308 is that the fluid contact does not typically damage the wafer, whereas a mechanical contact tends to warp and/or deform the wafer. Another advantage of the fluid contact is that it provides a relatively large contact surface area since the contact is continuous throughout the "cathode contact area." For example, the two (2) millimeter wide cathode contact area amounts to approximately a two (2) square-inch surface area. That is substantial considering how small the width of the "cathode contact area" is. Because of the relatively large contact surface area, the resistance of the contact is relatively small. This increases the current carrying capacity of the contact, which can lead to much higher plating rates. Yet another advantage of the conductive fluid contact is that the electrical contact is more uniform plating deposition across the surface of the wafer. This results in a more uniform plating deposition across the surface of the wafer. Still another advantage of the conductive fluid, particularly if it

TITLE: Method for creating and testing a combinatorial array employing individually addressable electrodes

----- KWIC -----

Brief Summary Text - B9TX (5):

Electroplating has been employed in small scale as well as industrial processes. For example, electroplating of precious metals to improve the appearance of an article or to create special effects is well known. Electroplating is also employed to improve the corrosion resistance of corrosive substances by depositing thin surface films of corrosion resistant metals such as zinc, tin, chromium, nickel and others. Wear resistant and friction modifying coatings of nickel, chromium, titanium and other metals and their alloys are used to improve the wear resistance of bearing surfaces. Electroplating is also employed in the electronics industry to improve or modify the electrical properties of substrates such as contacts, printed circuits, electrical conductors, and other electrical items in which specific surface or surface-to-substrate conductive properties are desired. Distinct metals are often electroplated onto metal surfaces to improve soldering characteristics or to facilitate subsequent coating by painting or application of other adhering films such as plastics, adhesives, rubber, or other materials.

### ABSTRACT

An electrochemical deposition and testing system consisting of individually addressable electrode arrays, a fully automated deposition head, and a parallel screening apparatus is described. The system is capable of synthesizing and screening millions of new compositions at an unprecedented rate.

release the airtight state of the plating chamber during wafer transferring, the mist in the plating chamber is scattered out of the plating chamber. Thus, in the conventional plating apparatus, there was a possibility that contamination caused by mist of plating solution was not sufficiently prevented, with the result that plating with high reliability was not performed.

[0009] Moreover, in the aforementioned plating apparatus, a processing object, for example, a semiconductor wafer is applied given voltage through a plurality of contact pins provided in a holding member for holding the processing object. Accordingly, there is a problem in which a nonuniform film is formed on the processing object or no plating is performed when electrical contact of contact pins to the processing object is poor.

[0010] As a method for checking the contact state of contact pins to the processing object, there is a method disclosed in Unexamined- Japanese Patent Application KOKAI Publication No. H11-181600. This is the method in which a resistance value between two contact pins connected to each other is measured by a resistance measuring device to confirm the contact state of contact pins from the resistance values.

[0011] The above method, however, is to confirm the contact state of the contact pins interposed between two contact pins. Accordingly, it is impossible to know which contact pin has contact failure. In order to check the contact state of each contact pin in detail, numerous resistance measuring devices must be used, and this makes the apparatus structure complicated. Thus, there was a possibility that the conventional plating apparatus did not confirm the passage of electric current through the processing object and the contact pins with ease and without fail, resulting that plating with high reliability was not performed.

#### SUMMARY OF THE INVENTION

[0012] With consideration given to the aforementioned problems, it is an object of the present invention to provide a processing apparatus and a processing system with high reliability.

[0013] Other object of the present invention is to provide a processing apparatus and a processing system with easy maintenance.

[0014] Another object of the present invention is to provide a processing apparatus and a processing system, which is capable of easy and sure checking of electrical contact state.

[0015] In order to attain the above objects, according to the present invention, there is provided a processing apparatus comprising a chamber having a first area for performing a delivery of a processing object between an outer section and the chamber, and a second area for providing given processing to the processing object; a process solution bath, provided in the second area, for reserving a process solution; a processing mechanism for providing predetermined processing to the processing object using the process solution in the second area; a sucking line, provided in the first area, for sucking an atmosphere of the first area in the vicinity of a boundary between the first area and the second area; and an exhaust line, provided in the second area, for exhausting atmosphere in the second area to the outer section in the vicinity of the boundary between the first area and the second area.

(57) ABSTRACT

A plating system is composed of a transfer device for performing transfer of a wafer, a plating unit and a washing/drying unit provided around the transfer device. Each unit is structured to be detachable from the plating system. The plating unit is divided into a wafer transfer section and a plating section by a separator, and atmosphere of each section is independently set.

small current flows.

[0089] The measuring device 424 is connected to the controller 318. The measuring device 424 sends obtained current value data between each contact pin 413a and each probe 418 to the controller 318. The controller 318 determines the contact (connection) state of each contact pin 413a from the current quantities.

[0090] For example, the controller 318 determines that the contact state of contact pin 413a is normal when the current value between the contact pin 413a and the corresponding probe 418 is more than a predetermined value. While, in the case where the current value is below the predetermined value, the controller 318 determines that the contact state of contact pin 413a is abnormal.

[0091] The controller 318 performs control of the overall apparatus such as continuation of plating or stop processing, and the like based on the determination result. This makes it possible to check the contact state of each contact pin 413a without fail, and to perform plating with high reliability.

[0092] An explanation will be next given of a plating method using the above-structured plating unit 104. First, the contact state of contact pin 413a of the cathode electrode 413 is checked before the wafer W is plated. As illustrated in FIG. 9A, the pressing tool 416 rises in the holding section 414. At this time, the pressing tool 416, the contact pin 413a, and the seal section 415 are spaced one another.

[0093] Next, as illustrated in FIG. 9B, the pressing tool 416 moves down. At the position corresponding to the contact pin 413a of the lower surface of the pressing tool 416, the first concave portion 416a is formed. At the position corresponding to the seal section 415 of the lower surface of the pressing tool 416, the second concave portion 416b is formed. Accordingly, when the pressing tool 416 moves down, the contact pin 413a is contained in the first concave portion 416a and the seal section 415 is contained in the second concave portion 416b. At this time, the probe 418 in the first concave portion 416a and the contact pin 413a are in contact with each other. In this state, the measuring device 424 measures the electrical resistance between each pair of contact pin 413a of the cathode electrode 413 and probe 418 sequentially.

[0094] The controller 318 determines that the contact state of contact pin 413a is normal when the current value between the contact pin 413a and the corresponding probe 418 is more than a predetermined value. While, in the case where the current value is below the predetermined value, the controller 318 determines that the contact state of contact pin 413a is abnormal. The controller 318 stops plating when determining that the contact state is abnormal, and continues plating when determining the contact state is normal.

[0095] After checking contact (connection), the pressing tool 416 rises and a space is formed among the pressing tool 416, the contact pin 413a, and the seal section 415. Then, as illustrated in FIG. 9C, the second wafer transfer apparatus 213 loads the wafer W into the plating unit 104 through the space and mounts the wafer W on the contact pins 413a and the seal sections 415.

[0096] Sequentially, as illustrated in FIG. 9D, the pressing tool 416 moves down and presses the wafer W from the above. This fixes the wafer W to be adhered to the seal section 415. Next, the holding section 414 moves down as holding the state that the pressing tool 416 presses the wafer W so that the

US-PAT-NO: 6146515

DOCUMENT-IDENTIFIER: US 6146515 A

TITLE: Power supply and method for producing non-periodic complex waveforms

----- KWIC -----

Detailed Description Text - DETX (23):

An optional process feedback system can be implemented to measure any plating variable, for instance, resistance barrier layers at the cathodic surface. Such information is fed back to the secondary rectification portion 330 in the form of a voltage or current signal. The output can then be modulated in proportion to the feedback signal and according to variables set by the user in order to compensate for plating process variables in a closed loop system. The user may view the feedback signal on the LCD display panel (or computer monitor), and set reference and factor parameters to determine the behavior of the system based on the equation:

US-PAT-NO: 6613214

DOCUMENT-IDENTIFIER: US 6613214 B2

TITLE: Electric contact element for electrochemical deposition system and method

----- KWIC -----

Detailed Description Text - DETX (15):

Although the electric contact ring 152 of the present invention is designed to resist deposit buildup on the inner electric contact elements 172, over multiple substrate plating cycles the substrate-electric contact element interface resistance may increase, eventually reaching an unacceptable value. An electronic sensor/alarms 204 can be connected across the external resistor 200 to monitor the voltage/current across the external resistor to address this problem. If the voltage/current across the external resistor 200 falls outside of a preset operating range that is indicative of a high substrate-electric contact element resistance, the sensor/alarms 204 triggers corrective measures such as shutting down the plating process until the problems are corrected by an operator. Alternatively, a separate controller can be connected to each electric contact element 165 and can be separately controlled and monitored to provide a uniform current distribution across the substrate. A very smart system (VSS) may also be used to modulate the current flow. The VSS typically comprises a processing unit and/or control current such as variable resistors, separate controllers, etc. As the physiochemical, and hence electrical, properties of the inner electric contact elements 172 change over time, the VSS processes and analyzes data feedback. The data is compared to pre-established setpoints and the VSS then makes appropriate current and voltage alterations to ensure uniform deposition.

### ABSTRACT

An apparatus and associated method for deposition of metal ions contained in an electrolyte solution to form a metal film primarily on a seed layer formed on at least a first side of a substrate. The substrate has a second side that is opposed to the first side and an edge joining the first side and the second side. The apparatus comprises a substrate holder system and an electric contact element. The electric contact element physically contacts one of the second side or the edge of the substrate. In one aspect, the substrate is rotated about its vertical axis when the seed layer of substrate is immersed in the electrolyte solution during the metal film deposition. In another aspect, the substrate is not rotated about its vertical axis when the seed layer on the substrate is immersed in the electrolyte solution during the metal film deposition. In different embodiments, the electric contact element contacts the seed layer on the second side of the substrate, a diffusion barrier layer on the second side of the substrate, or the seed layer on the edge of the substrate.

TITLE: Plating device

----- KWIC -----

Brief Summary Text - B9TX (17):

Further, it is preferable that the conduction detection device be provided with a contact resistance measuring device to measure contact resistance between a conductive layer on the plating surface of the substrate and individual feeding contacts so as to determine electrical conductivity properties of respective feeding contacts according to respective values of contact resistance measured by the contact resistance measuring device.

Drawing Description Text - D9TX (9):

FIG. 8 is a circuit diagram of a basic resistance measuring device to measure the resistance between the feeding contacts.

Drawing Description Text - D9TX (11):

FIG. 10 is a schematic wiring diagram of the circuits for contact resistance measuring and plating feeding for feeding contacts of the plating apparatus.

Drawing Description Text - D9TX (12):

FIG. 11 is a schematic circuit diagram of the contact resistance measuring device.

Detailed Description Text - D9TX (9):

A method for checking the conduction state between the conductive layer of the substrate 12 and the feeding contact 15 is to measure the resistance value between two feeding contacts 15. The resistance value between two feeding contacts 15 is a combined resistance value R0 which comprises of the contact resistances R1 and R3 between the substrate 12 and the respective feeding contacts 15, and the resistance R2 of the conductive layer itself on the substrate 12. Here, values of the contact resistances R1, R3 are only about several hundred milli-ohms (m.OMEGA.), therefore, measurements must be performed with precision.

Detailed Description Text - D9TX (15):

The combined resistance  $R0=R1+R2+R3$  is usually in a range of 700.about.900 m.OMEGA. and to measure this low level of resistance accurately, it is necessary to cancel out the wire resistance. FIG. 9 shows an equivalent circuit for explaining the method for canceling the wire resistance. In FIG. 9, r1, r2 show the resistance values of the wiring connecting the constant current circuit 32 to each of the feeding contacts 15, 15 (A, B). And r3, r4 show the resistance values of wiring connecting the amplifier 33 to each of the feeding contacts 15, 15 (A, B). The current flowing in the constant current circuit 32 is designated by I.sub.M, the current flowing in the amplifier 33 by

### (57) ABSTRACT

The present invention is to provide a conduction detection device that can detect electrical conductivity (contact condition) of feeding contacts with conductive layers of a substrate. The present invention also provides an electroplating apparatus, which is able to produce uniform currents to flow through each of feeding contacts. The apparatus has a plating vessel, in which an electrode is disposed opposite to a substrate which is affixed to a plating jig electrically through a plurality of feeding contacts for applying a specific voltage between the electrode and conductive layers provided on a plating surface of the substrate. Plating current flows from the plating jig through the feeding contacts to the substrate. A conduction detection device is provided to detect electrical conductive states between the plurality of feeding contacts and the conductive layer on the substrate.

DOCUMENT-IDENTIFIER: US 6500317 B1

TITLE: Plating apparatus for detecting the conductivity between plating contacts on a substrate

----- KWIC -----

## Brief Summary Text - B8TX (9):

To solve the above mentioned subject matter, there is provided a method for confirming conductivity state between a plating jig having a plurality of conducting pins and a substrate to be plated having a conductivity film, the substrate being mounted on the plating jig having a plurality of conducting pins such that the conducting pins contact the conductivity film thereon, the method comprising: disposing the conducting pins of the plating jig being electrically separated independently with each other; attaching an end of reverse-current blocking diode to wiring connecting to the conducting pins, and connecting to the other ends of the reverse-current blocking diodes together to wiring connecting to a plating power source; and measuring an electrical resistance between the wiring so as to measure the electrical resistance between conducting pins of the plating jig.

## Brief Summary Text - B9TX (10):

According to another aspect of the present invention, the conductivity state detector may comprise a contact resistance measuring device for measuring contact resistance between the feeder contacts and the conductive area on the surface of the substrate and detects the conductivity state of the feeder contacts based on the contact resistance measured by the contact resistance measuring device.

## Drawing Description Text - D8TX (10):

FIG. 9 shows an example of a basic circuit construction for measuring resistance values between feeder contacts;

## Drawing Description Text - D9TX (12):

FIG. 11 shows the wiring configuration for measuring contact resistance at the feeder contacts and supplying current for plating;

## Drawing Description Text - D10TX (13):

FIG. 12 shows an example circuit construction for a contact resistance measuring device disposed at the feeder contacts; and

## Detailed Description Text - D5TX (5):

A resistance measuring device 4-1 is connected between the wires 3-1 and 3-3. A resistance measuring device 4-2 is connected between the wires 3-2 and 3-4. A jig having the circuit configuration described above is disposed opposite the anode 13 in the plating solution Q contained in the plating bath 10 shown in FIG. 1. The jig conducts electric current supplied from the DC power source (plating power source) 14. When each of the conducting pins 2-1,

## ABSTRACT

The present invention provides a conductivity sensing device capable of detecting the conductivity (contact state) of the plurality of feeder contacts contacting the conductive area of the substrate, and a plating apparatus capable of forming a plating film of uniform thickness by supplying a uniform plating current through a plurality of feeder contacts.

Detailed Description Text - DETX (22):

The conducting members 765 are defined by a plurality of outer electrical contact pads 780 annularly disposed on the flange 762, a plurality of inner electrical contact pads 772 disposed on a portion of the substrate seating surface 768, and a plurality of embedded conducting connectors 776 which link the pads 772, 780 to one another. The conducting members 765 are isolated from one another by the insulative body 770. The insulative body may be made of a plastic such as polyvinylidene fluoride (PVDF), perfluoroalkoxy resin (PFA), TEFLON, RTM, (a registered trademark of the E.I. duPont de Nemours and Company) and TEFZEL-RTM. (a registered trademark of the E.I. duPont de Nemours and Company) or any other insulating material such as Alumina (Al.sub.2 O.sub.3) or other ceramics. The outer contact pads 780 are coupled to a power supply, not shown, to deliver current and voltage to the inner contact pads 772 via the connectors 776 during processing. In turn, the inner contact pads 772 supply the current and voltage to a substrate by maintaining contact around a peripheral portion of the substrate. Thus, in operation the conducting members 765 act as discrete current paths electrically connected to a substrate.

Detailed Description Text - DETX (29):

FIG. 9 is a perspective view of an alternative embodiment of a cathode contact ring 1800. The cathode contact ring 1800 comprises a conductive metal or a metal alloy, such as stainless steel, copper, silver, gold, platinum, titanium, tantalum, and other conductive materials, or a combination of conductive materials, such as stainless steel coated with platinum. The cathode contact ring 1800 includes an upper mounting portion 1810 adapted for mounting the cathode contact ring onto the substrate holder assembly and a lower substrate receiving portion 1820 adapted for receiving a substrate therein. The substrate receiving portion 1820 includes an annular substrate seating surface 1822 having a plurality of contact pads or bumps 1824 disposed thereon and preferably evenly spaced apart. When a substrate is positioned on the substrate seating surface 1822, the contact pads 1824 physically contact a peripheral region of the substrate to provide electrical contact to the electroplating seed layer on the substrate deposition surface. Preferably, the contact pads 1824 are coated with a noble metal, such as platinum or gold, that is resistant to oxidation.

DOCUMENT-IDENTIFIER: US 6436249 B1

TITLE: Clamshell apparatus for electrochemically treating semiconductor wafers

----- KWIC -----

Abstract Text - ABTX (1):

An apparatus for electroplating a wafer surface includes a cup having a central aperture defined by an inner perimeter, a compliant seal adjacent the inner perimeter, contacts adjacent the compliant seal and a cone attached to a rotatable spindle. The compliant seal forms a seal with the perimeter region of the wafer surface preventing plating solution from contaminating the edge, wafer backside and the contacts. As a further measure to prevent contamination, the region behind the compliant seal is pressurized. By rotating the wafer during electroplating, bubble entrapment on the banks of the surface is prevented. Further, the contacts can be arranged into banks of contacts and the resistivity between the contacts and the wafer surface. electrical connections between the contacts and the wafer surface.

TITLE - TI (1):

Clamshell apparatus for electrochemically treating semiconductor wafers

Brief Summary Text - BSTR (2):

The present invention relates generally to a method and apparatus for treating the surface of a substrate and more particularly to a method and apparatus for electroplating a layer on a semiconductor wafer.

Brief Summary Text - BSTR (4):

The manufacture of semiconductor devices requires the formation of electrical conductors on semiconductor wafers. For example, electrically conductive leads on the wafer are often formed by electroplating (depositing) an electrically conductive material such as copper on the wafer and into patterned trenches.

Brief Summary Text - BSTR (5):

Electroplating involves making electrical contact with the wafer surface upon which the electrically conductive material is to be deposited (hereinafter the "wafer plating surface"). To insure a uniform deposition, it is important that the electrical contact with the wafer plating surface be uniform and reliable.

ABSTRACT

An apparatus for electroplating a wafer surface includes a  
cup having a central aperture defined by an inner perimeter,  
a compliant seal adjacent the inner perimeter, contacts  
adjacent the compliant seal and a cone attached to a rotatable  
spindle. The compliant seal forms a seal with the perimeter  
region of the wafer surface preventing plating solution from  
contaminating the wafer edge, wafer backside and the con-  
tacts. As a further measure to prevent contamination, the  
region behind the compliant seal is pressurized. By rotating  
the wafer during electroplating, bubble entrapment on the  
wafer surface is prevented. Further, the contacts can be  
arranged into banks of contacts and the resistivity between  
banks can be tested to detect poor electrical connections  
between the contacts and the wafer surface.
